

Non-decision time (t_0) by target speed — hierarchical Bayesian (Method B): Paradigm 1 vs Paradigm 2
same chart, same y-scale per row; small dots = participants, big dot = group mean, bars = ± 1 SD

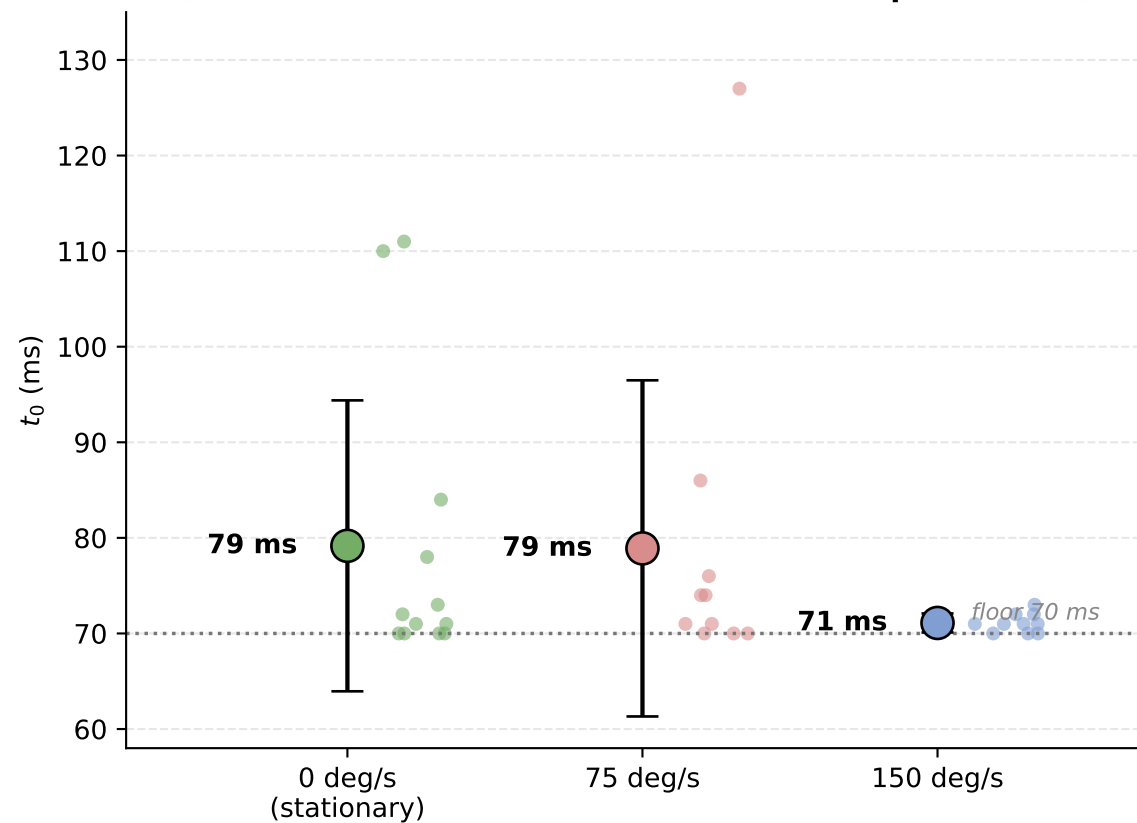

Paradigm 1 (CMT) — Hand t_0
0/48 cells at the floor · Friedman $p = 0.003$ ($n = 16$)

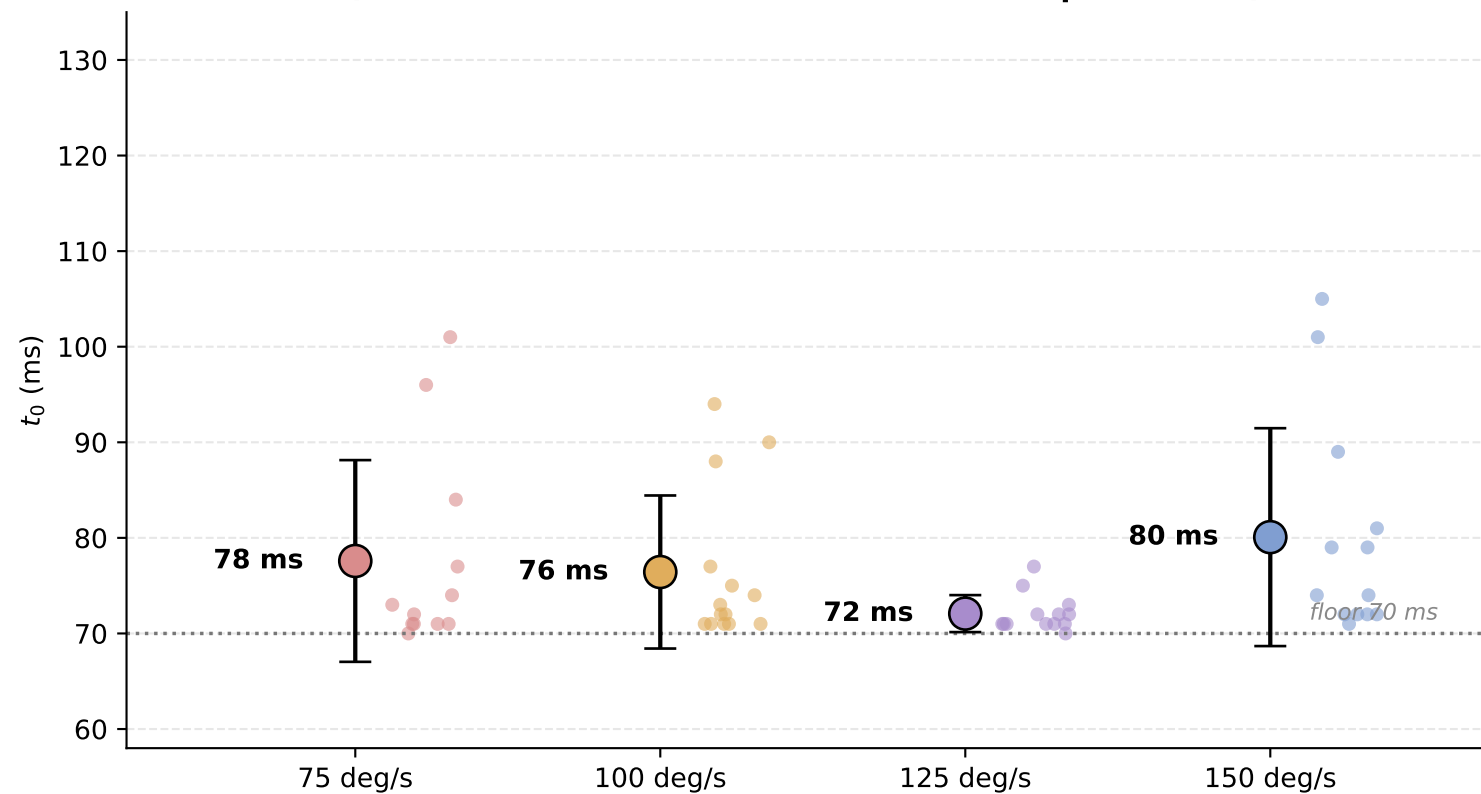

Paradigm 2 (CIR) — Hand t_0
0/64 cells at the floor · Friedman $p = 0.026$ ($n = 16$)

Paradigm 1 (CMT) — Saccade t_0
18/32 cells at the floor · Friedman $p = 0.747$ ($n = 7$)
(values held near the 70 ms floor — not a speed effect)

Paradigm 2 (CIR) — Saccade t_0
18/52 cells at the floor · Friedman $p = 0.006$ ($n = 12$)
(values held near the 70 ms floor — not a speed effect)

Saccade panels: single-component cells only (two-component cells excluded: P1 16, P2 12). Colours: 75 and 150 deg/s are the same colour in both paradigms.
