

LATER model for saccades — the saccade-native alternative to the shifted-Wald

Across participants the reciprobit is highly linear (median $r^2 = 0.97$): saccadic latencies are reciprocal-normal, exactly the LATER prediction. LATER models the whole latency as a rise to threshold, so there is no separate non-decision-time parameter and therefore no floor to hit. The trade-off: LATER's rate/threshold parameters are not comparable to the Wald's drift/boundary/non-decision, so this is a complementary saccade analysis, not a drop-in replacement for the cross-effector comparison.
