

# Why saccadic non-decision time floors: it is the distribution **SHAPE**, not the data (Paradigm 1)

implied  $t_0 = \text{mean RT} - 3 \cdot \text{SD} / \text{skewness}$  (forced by the Wald's skew-spread geometry)

## HAND (manual reaction time)

## EYE (saccadic reaction time)

Hand: skew/CV = 12.9, shape-implied  $t_0 = 191$  ms vs the 130 ms floor (above it, so  $t_0$  is identified). Eye: skew/CV = 3.4, shape-implied  $t_0 = 20$  ms vs the 70 ms floor (below it, so the model assigns almost all of the RT to the decision and  $t_0$  is pushed onto the floor). More trials cannot change this — it is set by the shape of the distribution (a pure Wald has skew/CV = 3).
