

Non-decision time (t_0) by target speed — MLE (Method A): Paradigm 1 vs Paradigm 2
same chart, same y-scale per row; small dots = participants, big dot = group mean, bars = ± 1 SD

Paradigm 1 (CMT) — Hand t_0
11/48 cells at the floor · Friedman $p = 0.105$ ($n = 16$)

Paradigm 2 (CIR) — Hand t_0
19/64 cells at the floor · Friedman $p = 0.398$ ($n = 16$)

Paradigm 1 (CMT) — Saccade t_0
24/48 cells at the floor · Friedman $p = 0.345$ ($n = 16$)
(values held near the 70 ms floor — not a speed effect)

Paradigm 2 (CIR) — Saccade t_0
29/64 cells at the floor · Friedman $p = 0.309$ ($n = 16$)
(values held near the 70 ms floor — not a speed effect)

Saccade panels: two-component cells use their regular component's t_0 , as in NDT_barchart. Colours: 75 and 150 deg/s are the same colour in both paradigms.
